Two-phase thermosyphons are passive refrigeration devices that transfer heat against gravity. Construction is typically a closed-ended tubular vessel charged with a two-phase working fluid. The vapor phase of the working fluid fills the majority of the interior of the vessel, with the liquid phase filling the minority of the volume.

The thermosyphon shown in Fig 1.1 is a two-phase loop with a compact evaporator that employs microfabricated boiling enhancement structures made of high thermal conductivity materials. The thermosyphon prototype was developed as a joint effort between Hewlett-Packard Laboratories, Georgia Institute of Technology and Thermacore.

Two-Phase Loop: Compact Thermosyphon - HP Labs

In the present paper, we investigate the overall thermal resistance of a closed two-phase thermosyphon using pure water and various water based nanofluids (of Al₂O₃, CuO and Laponite clay) as working fluids. We observed that all these nanofluids show inferior thermal performance than pure water.

Thermosiphon (or thermosyphon) is a method of passive heat exchange, based on natural convection, which circulates a fluid without the necessity of a mechanical pump. Thermosiphoning is used for circulation of liquids and volatile gases in heating and cooling applications such as heat pumps, water heaters, boilers and furnaces.

Thermosiphon - Wikipedia

Closed Loop Two Phase Thermosyphons (CLTPT) which have appeared in the technical literature in the last ten years are quoted and commented. The basic concepts related to the operation of vertical loop thermosyphons in connection with cooling systems can be originally found in works of the late nineties like Rossi and Polasek

Improvement in Performance of closed loop Thermosyphon

Among two-phase heat-transfer devices, such as heat pipes, loop heat pipes, oscillating heat pipes and thermosyphons, the last ones are the simplest both in design and manufacture and for the description of thermophysical and hydrodynamic processes observed in them.
